What is UML?

Born in 1994, standardized in 1998, official version (2.0) in 2005

A *de-facto* design language

› A semi-standard notation based on a meta-description of entities in a SW system

› Graphical notations

› Supports *divide-et-impera*

Useful because

› Can model different level of abstractions and dev phases: from specs to single classes

› Works both for top-down and bottom-up

› Language-independant

UML taxonomy

Three macro-areas

<u>Entities</u> (a.k.a.: the structure)

› Classes, interfaces

› Behavior (FSMs, interaction w/users)

› Grouping and packaging

› Notations and general information

<u>Relations</u>

› Association

› Dependency

› Generalization

› Implementation

<u>Diagrams</u>

› Same object/entity, different perspectives

› Partial representation, to "see things" under a different light

UML (standard) diagrams

Structural diagrams

› Use-cases/scenarios

› Notations for classes/objects/packages/components – From OOP   } later

› Deployment/components   } won't see these

Behavioral diagrams

› Sequence diagrams

› State diagrams

› Activity diagrams

Use-case diagrams

Use case modeling

Describe the interaction between the system and other actors

› Users, other external systems,....
› Can be either a picture, or a table (or both)

These are **not** system requirements!

› We model the expected behavior

› Also, useful for functional tests/verification

We want to clearly identify

› The boundaries of the system (behavioral and "physical")

› Actors/macro-entities

› Use-case scenarios

Graphical notation

> For every element, can/shall add a <u>brief</u> description

The right level of abstraction

First, identify the <u>Actors</u>, and model their interaction with the system

› Remember: actors are **external** to our system!

› ..even if we might model them internally, they're not under our control

Then, define multiple <u>Scenarios</u>

› They are a single instance of use-case
  – Define the (sequence of) evenths that happen in a specific ….scenario ☺
  – Scenario (and their events) define functional, and user assessment tests

› Distinguish between <u>main scenarios </u>(everything works correctly)

› …and <u>secondary scenarios </u>(extensions, or in case of errors)
  – «Optional parts» of the scenario
  – Can become a lot!

Scenario/UC diagrams

Define how the system interacts with the extern

› Operational conditions (also called "Operational Design Domain"), might also be standardized (see automotive)

› "Doesn't work"…but under which conditions? Which scenario?

› "It works <u>on my laptop</u>" – I <u>**do not want**</u> to hear this sentence anymore, ok?

We typically specify

› Pre-conditions, and post-conditions (i.e., states change)

› Guarantees both to be given, and assumed

  – Reliability, both ours and others', QoS, …

› Triggers to events

Example: Paolo's Casino

Use-case: users throwing dices

› User shall be able to bet

› User shall be able to throw dices
Table description

More structured, accompanies the image (or the image accompanies it)

› Unique ID

› Title

› Actors

› Pre-conditions

› Sequence of events
  – Triggers by actors
  – System responses

› Postconditions, exceptions
  – Also, state changes (e.g.., data storage in DB)

Table description (cont'd)

› Use case/scenario: UC1

› Actors: Actors 1 (starter), Actor 2

› Type: Primary, secondary, essential

› Description: …

Actions	Responses
1. Actor 1, Action X	
2. Actor 2, Action Y	
	3. Response to Action 2
4. Actor 1, Action Z	
	5. Response to Action 4
…	…

Paolo's Casino

› Use case/scenario: [Throwing dices] Bet

› Actors: Player (starter)

› Type: Essential

› Description: The player guesses a number, and places a bet with X money

Actions	Responses (Primary)
1. Player sets X money, and places the bet	
	2. The system accepts the bet
Exceptions (secondary)	
1. The number is not between 0 and 6	
2. The player does not have X money	
…	

Relations

› Association between actors and use cases

› Generalization between actors and use cases
  – Add feature/characteristics to the parent

› Inclusion of use-cases
  – <<includes>>

› Extension of use-cases
  – <<extends>>
Generalization between actors

› Children can participate to all use-cases

› And add more

PaoloCasino

Player
(free subscription)

Player
(paied subscription)

Bet

Throw

Edit Bet
Generalization between UCs

Can re-define steps and events

› ..or specialize the existing ones
Extensions

Used to express dependencies

› First, place the bet, then throw the dice

› Theorically, Player only "sees" the "throw the dice" functionality
Inclusion

Used to express grouping reusage

› We can also play/bet with cards, not only with dices
How do I identify UCs (and scenarios)?

Actor-based vs process-based identification

›   For every actor, model the interaction

         vs

›   For every interaction, identify the actors

Use case diagrams

›   Are the starting point for system designers

›   Gives a good approximation of the dimension and complexity of the system

›   We can write user guides out of them

This is an iterative process

Sequence diagrams

Sequence diagrams

› Focus on Actors, and the data they exchange with the system

› Describe the interaction, by means of Messages, objects, etc

› They describe the timeline of a scenario
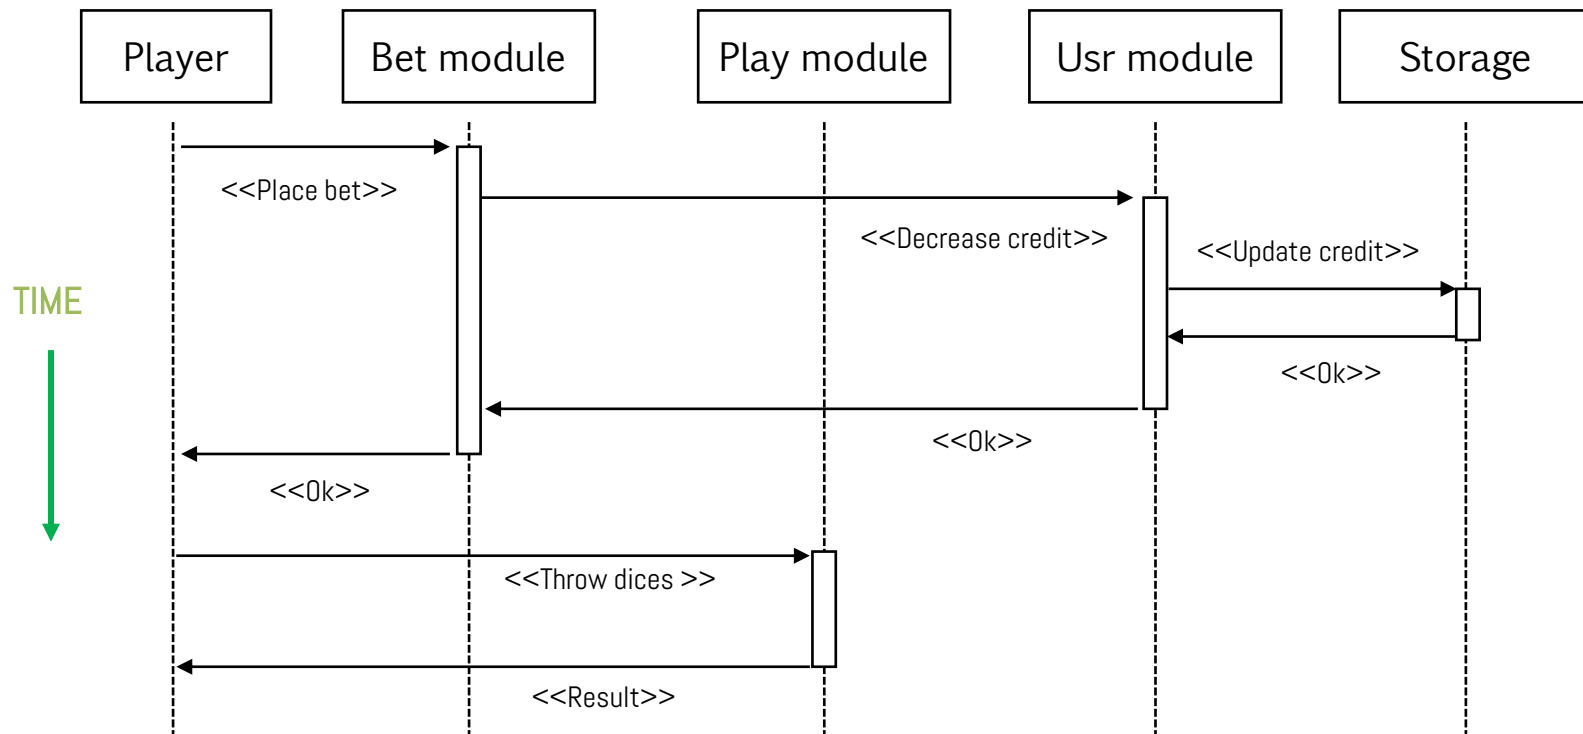

Sequence diagrams (cont'd)

Objects are entities, in our system

› Represented as a rectangle

› Can be Actors, Modules, Classes, DBs....
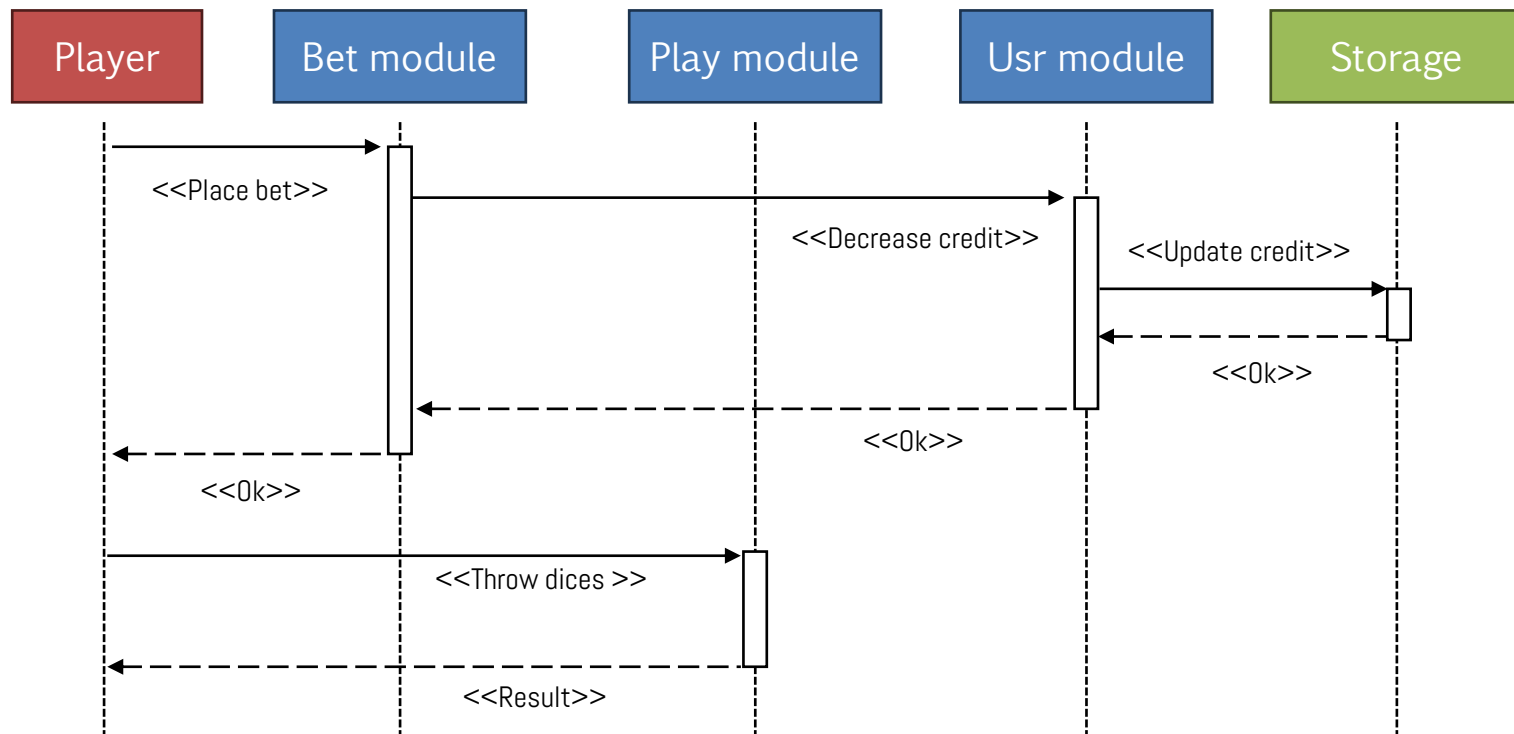

# Sequence diagrams (cont'd)

Lifeline represents when an entity exists

› For classes and objects, it is extremely meaningful

› Especially, if you don't have implicit memory mgmt, e.g., non-OO languages

Goodbye!

Sequence diagrams (cont'd)

Focus of control

› Rectangle on the lifeline

› The objects **synchronously locks** the interaction
Sequence diagrams (cont'd)

Stimula

› Represent calls, invokations (with brief description)

› For synchronous calls, dotted arrows are the return/response

› Not necessary to model also the transferred data

Sequence diagrams (cont'd)

Asynchronous focus of control

› Fire and forget semantics

› Ex: update user age

Stimula and messages

Stimula abstract messages, who represent/trigger **Actions**

› **Call/Invokation**, e.g., of a function, an endpoint etc

› **Return**

› **Send** a signal or a message

› **Create** or **destroy** objects

Message can be aggregated onto sequences

› To model complex interation / state changes

› In this case, might be useful to use numbering to explicit sequencing/ordering

<<1. Place bet>>

<<2. Throw dices >>

Types of messages

› Constructors, destructors

– For objects

› Read/query

› Update

› Collaborate / trigger an action

› Iterative (e.g., to specify that the entity on which we work is a list of items such as Java Arrays, Dictionaries, Lists)

› Marked with *****

Example: HTTP verbs

› POST, GET, UPDATE, DELETE (CRUD)
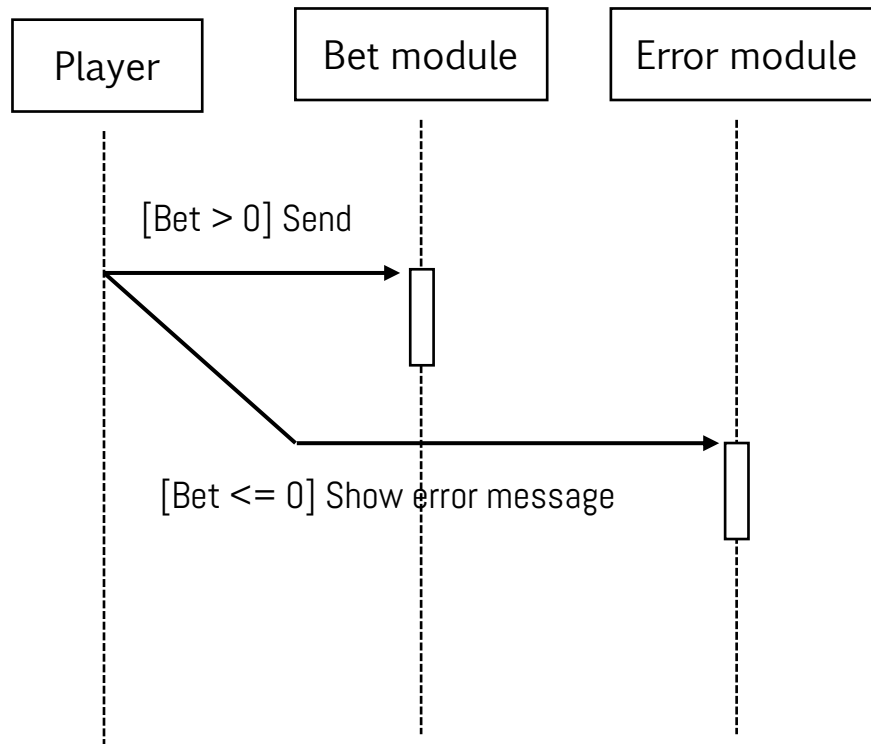

› But also PATCH, PUT, OPTIONS, …

Homework

Write the sequential diagram of a simple web server

› That supports all HTTP verbs on a sample endpoint

› https://<myserviceurl>/me

› E.g., handle user infos
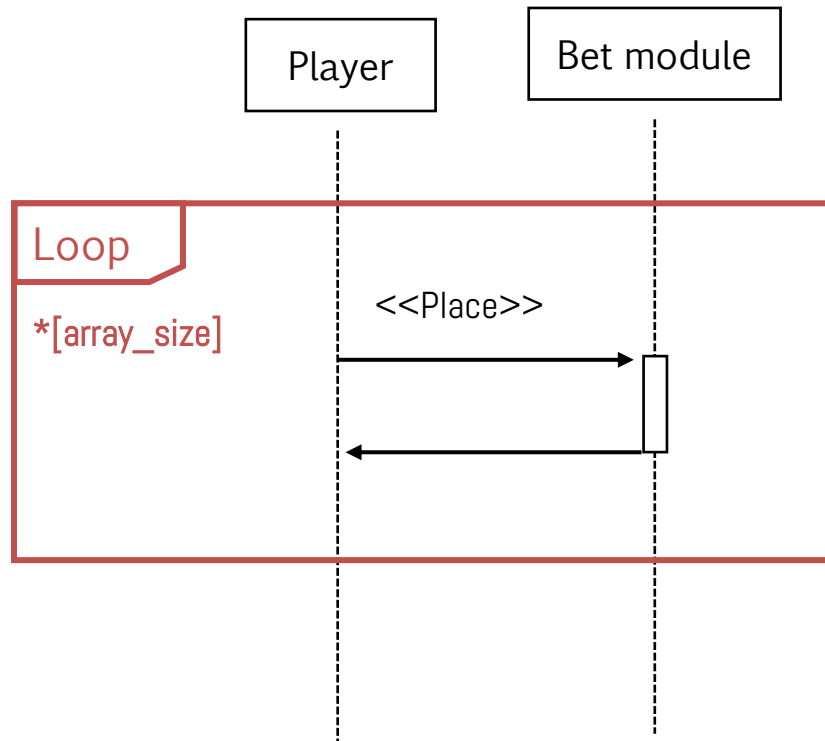

Conditional execution

› IFs are represented as []

Loops

Loops are represented as *[], and squares
> E.g., Place multiple bets by a list

```
        ┌──────────┐        ┌──────────────┐
        │  Player  │        │  Bet module  │
        └──────────┘        └──────────────┘
             ┆                     ┆
    ┌────────┆─────────────────────┆──────────┐
    │ Loop   ┆                     ┆          │
    │        ┆      <<Place>>      ┆          │
    │*[array_size]─────────────────▶┐         │
    │        ┆                     │█│        │
    │        ◀─────────────────────┘          │
    │        ┆                     ┆          │
    └────────┆─────────────────────┆──────────┘
             ┆                     ┆
```

Recursion

Some module

State diagrams

Stateful entities

State diagram to represent the lifecycle of an entity, typically classes/objects, by means of

› Events and Actions

› States

› Transitions

› Guards

State defined as:

a consistent, meaningful set of attributes of an entity/object, that affects its behavior

› Initial and end pseudo-states

› Initial state after creation/boot, etc

› End state might not exist (for persistent entities)

Graphical representation

By standard, a rounded square

› (fill with useful information/state/behavior)

nome dello stato

azioni di ingresso e
di uscita
transizioni interne

attività interna

Immissione Password

Entry/ visualizza password
Exit/ valida password
tastoAlfabetico/ echo "*"
help/ visualizza help
Do/ get
Sintassi dell'azione: evento/ azione
Sintassi dell'attività: Do/ attività
Or (non-standard) circles/ovals

› Useful when we don't have many details

› System-wide

Arcs - State transitions

$$E\ [C]\ /\ A$$

S_1 S_2
This means:

› If we are in <u>State</u> **S1**

› And <u>Event</u>/Trigger **E** happens

› If <u>Condition</u>/Guard **C** is satisfied

› Then we execute <u>Action</u> **A**, and we enter State **S2**
Transitions and guards

event [parameters] [guard] / action

› Events can have <u>parameters</u>

› Guards are conditions that "block" the transition, if not satisfied

› Action is a (typically small) piece of computation task that is executed as soon as transition is triggered
  – States can also contain (more complex) activities!

Events

› Trigger state transitions

› In Sequence Diagrams, modeled as Message
› Together with States, trigger object responses (Mealy vs. Moore...)

```
┌─────────────────────────────────────────────────────────┐
│  ┌──────────────────┐    placeBet()   ┌──────────────┐   │
│  │  $$ allocated     │ ──────────────> │ In progress  │   │
│  ├──────────────────┤                 ├──────────────┤   │
│  │                  │                 │              │   │
│  └──────────────────┘                 └──────────────┘   │
└─────────────────────────────────────────────────────────┘
```

They can be:

› Synchronoous method invokation ("<u>call</u>")

› Asynchronoous method invokation ("<u>signal</u>")
   – ex: throw exception, interrupts

› A condition turning true or false ("<u>change event</u>")

› An expired timer/counter ("elapsed <u>time event</u>")

State diagram:

ActiveRegularCustomer — when (30 days past due) → **Delinquent**

ActiveRegularCustomer — when (purchases > $1000 in past 6 years) → **ActivePreferredCustomer**

ActivePreferredCustomer — when (60 days past due) → **Delinquent**

ActivePreferredCustomer ---- predefined event "when"

Coperto — [saldo < 0] → **Scoperto**

Congelato

Sold

after(3 days)

Unsold

predefined event "after"

41

Activities and Actions

› Inside states, there can be

Activities

› Non-atomic

› (Typically) they do not alter object state

Actions

› Smaller, atomic

› They alter the object state

Actions

Entry: executed as soon as the object enters a given state

› entry/action name

Exit: executed as soon ase the object exits from a State, due to a transition

› exit/action name

Do: executed as soon as the object is in a State

› do/action name

Include: invokes a «submachine», another state diagram

Event: actions happen as a response to an Event/trigger

nome dello stato

azioni di ingresso e di uscita

transizioni interne

attività interna

Immissione Password
Entry/ visualizza password
Exit/ valida password
tastoAlfabetico/ echo "*"
help/ visualizza help
Do/ get
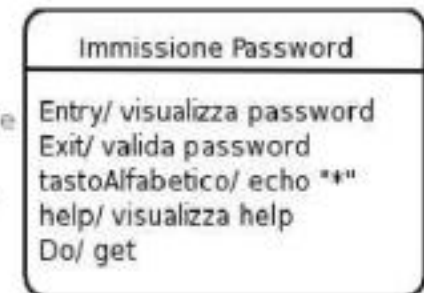

Sintassi dell'azione: **evento/ azione**
Sintassi dell'attività: **Do/ attività**

Actions: example
Actions: sequence

When an event triggers a transition

› Executing activities are interrupted ("gracefully", we hope...)

› Run the Exit action of the «old» state

› Run the Event action

› Run the Entry action of the «new» state

› Run Do actions of the «new» state

Actions: success vs. failure
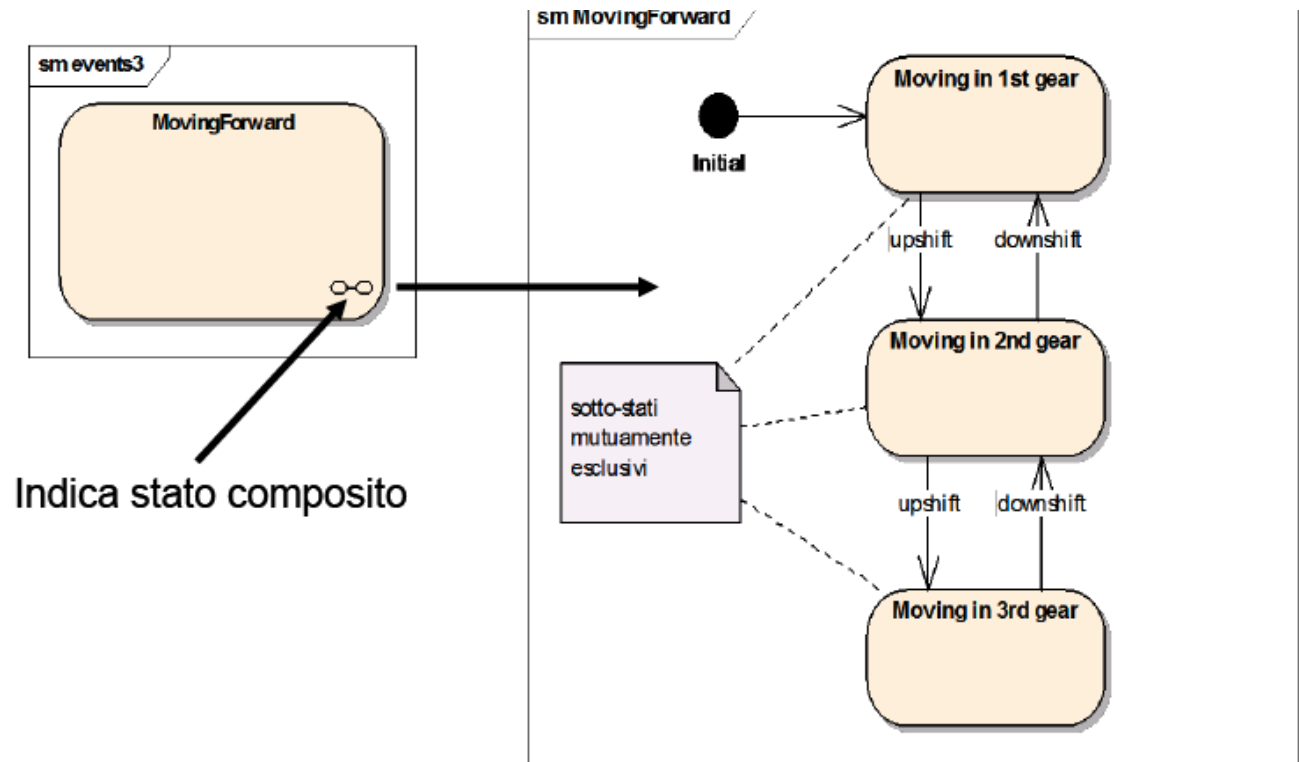

› 2 scenarios (modeled in sequence diagrams)
Action: success scenario
# Action: failure scenario
# States and mutual exclusion
› Or decomposition (of sub-states)

Concurrent states
# Alternative states/scenarios

Composite states

Conditional branching

› Same trigger/event, different conditions, bring to different states

Activity diagrams

Activity Diagrams in a nutshell

Model the behavior of any entity in the system, for every state

› "Object-Oriented" flow diagrams

› They include (timing and spatial) dependencies

› Give more detail of activities (and sub-activities) happen in every state, under inputs

Actions, and transitions
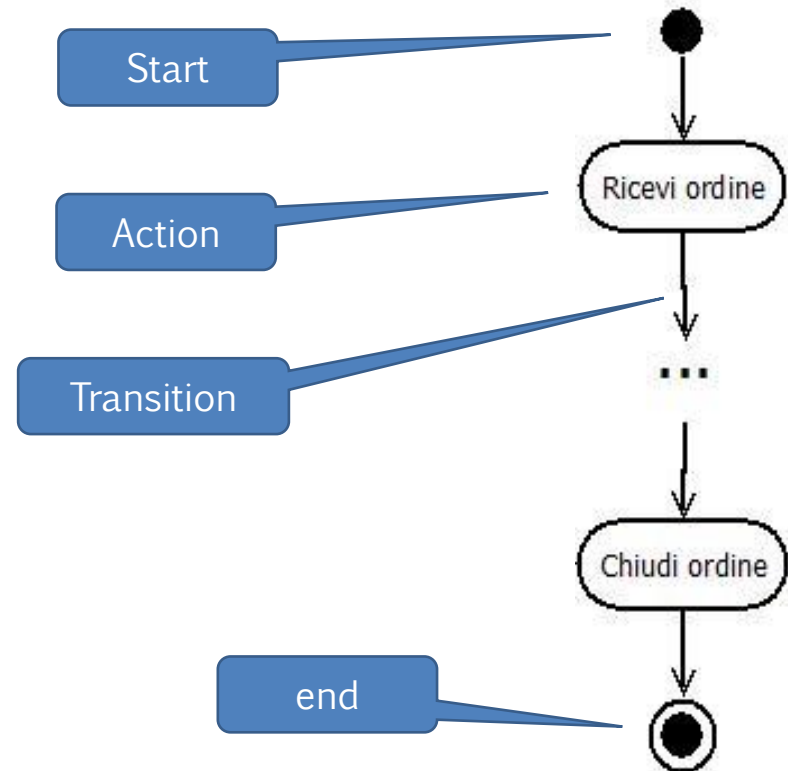

Action states are atomic activities

› Cannot be split

› Cannot be interrupted (preempted)

› (In the model) happen instantly

Special states

› Start/end state

Transition

› When Action states ends

Start

Action

Transition

Ricevi ordine

...

Chiudi ordine

end

Branching/Merging
Branching based on condition

› Captures IF-ELSE semantics

› Rhombus: one-to-many
Merging

› Rhombus: many-to-one

Important

› You do not have to model the whole application!

› Choosing the right abstraction level, lets you cut the clutter
Fork/Join

Model concurrent actions

› Implemented with parallel threads/processes..

› Join point represent

› (We'll go back to this..)

# Sub-activity states

Group activity states /subdiagram into macro functionalities

› Non atomic

› Can be interrupted

› Non-zero execution time

# The full example

Swimlanes

Group activities into <u>areas</u>

› Partition the activity diagram

What do we model with areas?

› Use cases

› Classes/Objects

› Components

› Business units

› Roles

› Here, areas = business units

From Activity diagrams to Sequence diagrams

› Activity diagrams identify scenaries, and we can/must write a Sequence diagrams for each of them!

› Can use areas to model scenaries/use cases

Class diagrams

Object diagrams

Package diagrams
